- $\Sigma$  - finite non-empty set, **alphabet**
- $\Sigma^*$  - the **free monoid generated by  $\Sigma$**

## Example

$$\Sigma = \{a, b\}$$

$$\Sigma^* = \{\lambda, a, b, aa, ab, ba, bb, \dots\}$$

- $\Sigma$  - finite non-empty set, **alphabet**
- $\Sigma^*$  - the **free monoid generated by  $\Sigma$**

## Example

$$\Sigma = \{a, b\}$$

$$\Sigma^* = \{\lambda, a, b, aa, ab, ba, bb, \dots\}$$

- $L \subseteq \Sigma^*$ : **language**

- $\Sigma$  - finite non-empty set, **alphabet**
- $\Sigma^*$  - the **free monoid generated by  $\Sigma$**

## Example

$$\Sigma = \{a, b\}$$

$$\Sigma^* = \{\lambda, a, b, aa, ab, ba, bb, \dots\}$$

- $L \subseteq \Sigma^*$ : **language**
- $w^0 = \lambda$  and  $w^{n+1} = w^n w, \forall n \geq 0$ : **powers** of a word  
 $w \in \Sigma^*$

- $\Sigma$  - finite non-empty set, **alphabet**
- $\Sigma^*$  - the **free monoid generated by  $\Sigma$**

## Example

$$\Sigma = \{a, b\}$$

$$\Sigma^* = \{\lambda, a, b, aa, ab, ba, bb, \dots\}$$

- $L \subseteq \Sigma^*$ : **language**
- $w^0 = \lambda$  and  $w^{n+1} = w^n w$ ,  $\forall n \geq 0$ : **powers** of a word  
 $w \in \Sigma^*$
- $w^* = \{w^0, w^1, w^2, \dots\}$ .

A **finite automaton** is a quintuple  $\mathcal{A} = \langle \Sigma, Q, q_0, F, \sigma \rangle$  where

- $\Sigma$  is the *input alphabet*,
- $Q$  is a finite set called the *set of states*,
- $q_0 \in Q$  is the *initial state*,
- $F \subseteq Q$  is the *set of final states* and
- $\sigma : Q \times \Sigma \rightarrow 2^Q$  is the *transition function*.

A **finite automaton** is a quintuple  $\mathcal{A} = \langle \Sigma, Q, q_0, F, \sigma \rangle$  where

- $\Sigma$  is the *input alphabet*,
- $Q$  is a finite set called the *set of states*,
- $q_0 \in Q$  is the *initial state*,
- $F \subseteq Q$  is the *set of final states* and
- $\sigma : Q \times \Sigma \rightarrow 2^Q$  is the *transition function*.

If  $\forall q \in Q, a \in \Sigma : |\sigma(q, a)| \leq 1$  then  $\mathcal{A}$  is deterministic, otherwise nondeterministic.

$L(\mathcal{A})$ , the **language accepted** by the finite automaton  $\mathcal{A}$  is the set of all words  $a_1 a_2 \dots a_n$  ( $a_i \in \Sigma$ ), such that there exist states  $p_0, \dots, p_n$  such that

$$\forall i \in \{1, \dots, n\} : p_i \in \sigma(p_{i-1}, a_i),$$

$$p_0 = q_0, p_n \in F$$

$L(\mathcal{A})$ , the **language accepted** by the finite automaton  $\mathcal{A}$  is the set of all words  $a_1 a_2 \dots a_n$  ( $a_i \in \Sigma$ ), such that there exist states  $p_0, \dots, p_n$  such that

$$\forall i \in \{1, \dots, n\} : p_i \in \sigma(p_{i-1}, a_i),$$

$$p_0 = q_0, p_n \in F$$

A language is **regular** iff it is accepted by a finite automaton.

## Example

$\mathcal{A} = \langle \{0, 1\}, \{q_0, q_1\}, q_0, \{q_1\}, \sigma \rangle$ , where the transition function  $\sigma$  is:

$\sigma$	0	1
$q_0$	$q_0$	$q_1$
$q_1$	$q_1$	$q_0$

$$L(\mathcal{A}) = \{w \in \Sigma^* \mid \exists k \geq 0 : |w|_1 = 2k + 1\},$$

that is all binary words having an odd number of 1's.

## Quasi order (preorder): reflexive and transitive binary relation

**Quasi order** (preorder): reflexive and transitive binary relation

**Well** quasi order: any infinite sequence of elements  $x_0, x_1, \dots$  contains an increasing pair  $x_i \leq x_j$  with  $i < j$ . So:

- no infinite decreasing series
- no antichain (infinite series of pairwise incomparable elements)

## Definition

For  $u, v \in \Sigma^*$ :

$u \leq v$ :  $u$  is a **subsequence** (subword, scattered subword) of  $v$  if  $u = x_1 \cdots x_n$  and  $v = y_0 x_1 y_1 x_2 y_2 \cdots y_n$  for some  $x_i, y_j \in \Sigma^*$ .  
 $v$  is a supersequence of  $u$ .

## Definition

For  $u, v \in \Sigma^*$ :

$u \leq v$ :  $u$  is a **subsequence** (subword, scattered subword) of  $v$  if  $u = x_1 \cdots x_n$  and  $v = y_0 x_1 y_1 x_2 y_2 \cdots y_n$  for some  $x_i, y_j \in \Sigma^*$ .  
 $v$  is a supersequence of  $u$ .

## Definition

Words  $w_1, w_2, \dots, w_n$  form a **basis** of  $L$  if:

- $\forall v \in L, \forall i \in \{1, \dots, n\} : v \leq w_i \Rightarrow v = w_i$  - they are all minimal in  $L$  and
- $\forall v \in L, \exists i \in \{1, \dots, n\} : w_i \leq v$  - they generate  $L$

- duplications considered again by Dassow, Mitrana, Păun in '99

- copying systems introduced by Ehrenfeucht and Rozenberg in '84
- Bovet and Varricchio '92: copy languages are regular over a binary alphabet
- duplications considered again by Dassow, Mitrana, Păun in '99
- they show regularity of duplication closure of any binary word

## Theorem (Bovet, Varricchio)

For an *arbitrary* language  $L \subseteq \{a, b\}^*$ , the language  $L^{\rightarrow}$  is regular.

The argument: first show that **duplication over a binary alphabet is a well-quasi order on words**,

## Theorem (Bovet, Varricchio)

For an *arbitrary* language  $L \subseteq \{a, b\}^*$ , the language  $L^{\rightarrow}$  is regular.

The argument: first show that **duplication over a binary alphabet is a well-quasi order on words**, then use the generalization of the Myhill-Nerode theorem:

## Theorem (Ehrenfeucht, Haussler, Rozenberg)

A language  $L$  of a finitely generated free monoid is regular if and only if it is upwards closed with respect to a monotone well quasi order.

Mathematical hairpin concept (Păun et al., 1991): a word in which some suffix is the mirrored complement of a non-overlapping factor.

---

<sup>1</sup>or more generally, a regular language

Mathematical hairpin concept (Păun et al., 1991): a word in which some suffix is the mirrored complement of a non-overlapping factor.

**Hairpin completion** extends such a word into a pseudopalindrome with a non-matching part in the middle.

---

<sup>1</sup>or more generally, a regular language

Mathematical hairpin concept (Păun et al., 1991): a word in which some suffix is the mirrored complement of a non-overlapping factor.

**Hairpin completion** extends such a word into a pseudopalindrome with a non-matching part in the middle.

Thoroughly investigated in a series of papers; most basic algorithmic questions answered (Cheptea et al., Diekert et al.)

---

<sup>1</sup>or more generally, a regular language

Mathematical hairpin concept (Păun et al., 1991): a word in which some suffix is the mirrored complement of a non-overlapping factor.

**Hairpin completion** extends such a word into a pseudopalindrome with a non-matching part in the middle.

Thoroughly investigated in a series of papers; most basic algorithmic questions answered (Cheptea et al., Diekert et al.)

Noteworthy exception: “given a word<sup>1</sup>, can we decide whether the **iterated** application of the operation leads to a regular language?”

---

<sup>1</sup>or more generally, a regular language

Mathematical hairpin concept (Păun et al., 1991): a word in which some suffix is the mirrored complement of a non-overlapping factor.

**Hairpin completion** extends such a word into a pseudopalindrome with a non-matching part in the middle.

Thoroughly investigated in a series of papers; most basic algorithmic questions answered (Cheptea et al., Diekert et al.)

Noteworthy exception: “given a word<sup>1</sup>, can we decide whether the **iterated** application of the operation leads to a regular language?”

Approach it by a simpler operation, **pseudopalindromic completion** (F, Manea, Mercas, Shiskishima-Tsuji, 2014)

---

<sup>1</sup>or more generally, a regular language

*palindrome*:  $w = w_1 \dots w_n = w_n \dots w_1 = w^R$

For  $\theta : \Sigma^* \rightarrow \Sigma^*$ , we say that  $\theta$  is:

*involution*:  $\theta^2(w) = w$

*antimorphism*:  $\theta(w) = \theta(w_n) \dots \theta(w_1)$

*pseudopalindrome*:  $w = \theta(w_1 \dots w_n) = \theta(w_n) \dots \theta(w_1) = w^R$

## Definition

## Example

$\bar{a}a\bar{a}a$

- Step 1:  $\{a\bar{a}a\bar{a}, \bar{a}a\bar{a}a\}$
- Step 2:  $\{a\bar{a}a\bar{a}a\bar{a}, \bar{a}a\bar{a}a\bar{a}a\}$
- So forth ...  $(\bar{a}a)^n \cup (a\bar{a})^n$  for  $n \geq 2$

## Example

$\bar{a}a\bar{a}\bar{a}\bar{a}$

- Step 1:  $\{a\bar{a}a\bar{a}, \bar{a}a\bar{a}a\}$
- Step 2:  $\{a\bar{a}a\bar{a}a\bar{a}, \bar{a}a\bar{a}a\bar{a}a\}$
- So forth ...  $(\bar{a}a)^n \cup (a\bar{a})^n$  for  $n \geq 2$

Along the lines of the characterization of palindromic languages by [Horváth, Karhumäki, Kleijn 1987], we can characterize pseudopalindromic ones:

## Theorem

*A regular language  $L \subseteq \Sigma^*$  is pseudopalindromic, iff it is a union of finitely many languages of the form  $L_p = \{p\}$  or  $L_{r,s,q} = qr(sr)^*q^R$  where  $p$ ,  $r$  and  $s$  are pseudopalindromes, and  $q$  is an arbitrary word.*

## Theorem

$w^\times$  is regular iff  $w$  has at most one pseudopalindromic prefix or one suffix, or for all words  $w' \in w^{\times 1}$  there exist unique pseudopalindromes  $p$  and  $q$  with  $|p| \geq 2$ , such that:

- $w' \in p(qp)^+$
- $w'$  has no pseudopalindromic prefixes except for the words in  $p(qp)^*$ .

## Theorem

For a regular language  $L$ , its iterated pseudopalindromic completion  $L^\times$  is regular if and only if  $L$  can be written as the union of disjoint regular languages  $L'$ ,  $L''$ , and  $L'''$ , where

- $L'' = \{w \in L \mid w^{\times \leq 1} = w^\times\}$  and the completion of every word in  $L''$  is a subset of a finite union of languages of the form  $up(qp)^*\bar{u}$ , where  $upqp\bar{u}$  has no pseudopalindromic prefixes and  $p, q$  are pseudopalindromes;
- $L''' = \{w \in L \mid w^\times \setminus (w^{\times 1}) \neq \emptyset\}$  and, for an integer  $m \geq 0$  depending on  $L$  and pseudopalindromes  $p_i, q_i$  such that  $p_i q_i$  have only one nontrivial prefix and only one nontrivial suffix, the completion of every word in  $L'''$  is a subset of  $\bigcup_{i=1}^m p_i (q_i p_i)^+$ ;
- $L' = L'^{\times \leq 1} = L \setminus (L'' \cup L''')$ .

## Theorem

*Given a regular language  $L$ , it is decidable whether  $L = L^\times$ .*

## Theorem

*Given a regular language  $L$ , it is decidable whether  $L = L^\times$ .*

## Theorem

*Given a regular language  $L$ , it is decidable whether  $L^\times$  is regular. If the answer is YES, we can construct an automaton accepting  $L^\times$ .*

## Definition

A word  $p$  is **primitive** if there is no word  $q \neq p$  and no positive integer  $n$  such that  $p = q^n$ .

## Definition

A word  $p$  is **primitive** if there is no word  $q \neq p$  and no positive integer  $n$  such that  $p = q^n$ .

## Definition

The (primitive) **root** of a word  $p \in \Sigma^+$  is the unique primitive word  $q$  such that  $p = q^n$  for some  $n \geq 1$ .  $\sqrt{p}$  denotes the root of  $p$ . For a language  $L$ ,  $\sqrt{L} = \{\sqrt{p} : p \in L\}$  is the root of  $L$ .

## Definition

## Theorem

*Let  $L$  be a regular language. Then  $\text{pow}(L)$  is regular if and only if  $\text{pow}(L) \setminus L$  is a regular language with finite primitive root.*

## Theorem

*Let  $L$  be a regular language. Then  $\text{pow}(L)$  is regular if and only if  $\text{pow}(L) \setminus L$  is a regular language with finite primitive root.*

## Lemma

*Let  $L$  be a regular language given by an NFA having  $n$  states. If  $\text{pow}(L)$  is regular, then we have*

$$\text{pow}(L) \subseteq L \cup \{\sqrt{u}^i \mid u \in L \wedge |u| \leq \max(n^2, m) \wedge i \geq 1\},$$

*where  $m$  is the size of  $\text{Synt}(L)$ .*

## Remark

*Let  $L$  be a regular language given by an NFA having  $n$  states. If  $\text{pow}(L)$  is regular, then we have*

$$\text{pow}(L) \subseteq L \cup \{u^i \mid u \in L \wedge |u| \leq 2^{n^2} \wedge i \geq 1\}.$$

$$\text{pow}(L) \subseteq L \cup \{u^i \mid u \in L \wedge |u| \leq 2^{n^2} \wedge i \geq 1\}.$$

We can effectively find the root of  $\text{pow}(L) \setminus L$ .

## Lemma (Calbrix, Nivat)

Let  $L$  be a regular language of  $\Sigma^*$ . Then  $\text{pow}(L) = L$  if and only if there are regular languages  $(L_i)_{1 \leq i \leq n}$  such that  $L = \bigcup_{i=1}^n L_i^+$ .

For a regular language  $L$  it is decidable whether  $\text{pow}(L) = L$ .

## Theorem

*For a regular language  $L$  it is decidable whether  $\text{pow}(L)$  is regular.*

Algorithm:

Input: an NFA  $\mathcal{A} = \{\Sigma, Q, q_0, F, \sigma\}$ .

Output: "YES", if  $\text{pow}(L(\mathcal{A}))$  is regular, and "NO" otherwise.

①  $U = \emptyset$  root of  $\text{pow}(L) \setminus L$

## Theorem

*For a regular language  $L$  it is decidable whether  $\text{pow}(L)$  is regular.*

Algorithm:

Input: an NFA  $\mathcal{A} = \{\Sigma, Q, q_0, F, \sigma\}$ .

Output: "YES", if  $\text{pow}(L(\mathcal{A}))$  is regular, and "NO" otherwise.

- 1  $U = \emptyset$  root of  $\text{pow}(L) \setminus L$
- 2 FOR all words  $w \in L(\mathcal{A})$  shorter than  $2^{|Q|^2}$ :

## Theorem

*For a regular language  $L$  it is decidable whether  $\text{pow}(L)$  is regular.*

Algorithm:

Input: an NFA  $\mathcal{A} = \{\Sigma, Q, q_0, F, \sigma\}$ .

Output: “YES”, if  $\text{pow}(L(\mathcal{A}))$  is regular, and “NO” otherwise.

- ①  $U = \emptyset$  root of  $\text{pow}(L) \setminus L$
- ② FOR all words  $w \in L(\mathcal{A})$  shorter than  $2^{|Q|^2}$ :
- ③ IF  $w^* \setminus L(\mathcal{A}) \neq \emptyset$  THEN:
